Motivation

- ID-associated data are sequences of entries, and each entry is semantically associated with a unique ID. Examples are user IDs in user behaviour logs of mobile applications and device IDs in sensor records of self-driving cars.
- Nowadays, many big data applications generate such types of ID-associated data at high speed. Typically, most queries over ID-associated data are ID-centric – they retrieve and analyze data of a specific group of IDs over a period of time.
- To generate valuable insights from such data timely, the system needs to ingest high volumes of them with low latency, and support real-time analysis over them efficiently.

Demonstration Interface

The screenshot shows the PARAFLOW interface with two main sections: Overview and Nodes. The Overview section includes a Disk Usage pie chart (20.0% red, 30.0% yellow, 30.0% green, 10.0% blue), a Memory Usage pie chart (40.0% blue, 50.0% grey), and three status boxes: Live Nodes (26), Lost Nodes (0), and Dead Nodes (0). Below these are Kafka (v.1.1.1, 8 nodes), Loader (v.2.7.3, 16 nodes), and Presto (v.0.192, 17 nodes) metrics. The Nodes section lists two hosts: dbiir01 (Coordinator, 10 Oct 2018, Running) and dbiir02 (Kafka, 10 Oct 2018, Running).

The screenshot shows the PARAFLOW interface with a Query Console tab active. It displays a SQL-like query: `SHOW SCHEMAS;`. Below the query is a "Execute" button and a "Query Result" section which is currently empty. At the bottom, there are links for Documentation, FAQ, and Source code.

System Architecture

Key Techniques

Fiber Partitioning

The partitioning scheme is based on the consistent hashing. For each data entry, a hash function is applied to get a hash value of its ID, and the range of hash values is split into k intervals, mapping to k fibers.

Parallel Ingestion Pipeline

Data pulled from Kafka are maintained as fiber streams in separate threads. In each thread, data are sorted by their associated IDs and generation time. Once the sorted buffer reaches its max size or user-defined lifetime (elapsed time since the last reset), it compacts all data into the memory store and resets.

In-Memory Columnar Storage

Memory store organizes data as columnar segments (on-heap, off-heap, on-disk). To reduce memory footprints, lightweight compression schemes such as run length encoding, bit packing, and dictionary encoding are utilized to compress segments. With little overhead, queries can run directly on these lightweight compressed segments.
